          -1.7126e+00, -1.7126e+00]]]]) tensor([0, 7, 1, 1, 6, 6, 3, 7, 3, 4, 0, 8,
6, 1, 8, 8])
```

3. Using GPUs

We first check whether a GPU is available using torch.cuda.is_available(). If one is available, computations are assigned to the CUDA device (GPU); otherwise,the program falls back to the CPU.

In [8]:
```
if torch.cuda.is_available():
    device = torch.device('cuda')
else:
    device = torch.device('cpu')
print(device)
```

```
cuda
```

3.1 Show images

Here, we store the list of CIFAR-10 class names (airplane, car, bird, etc.) so we can allow mapping numeric labels to readable class names.

Then we traspose the image tensor from (C, H, W) to (H, W, C), so we can store the images in channel first format, this conversion is necessary for visualization.

Finally, the code selects a random index from the test dataset and allows us to visualize a random example image se we can visualize the dataset diversity and debug preprocessing steps when training the model.

In [9]:
```
classes = test_loader.dataset.classes
def plot_figure(image):
    plt.imshow(np.transpose(image,(1,2,0)))
    plt.axis('off')
    plt.show()

rnd_sample_idx = np.random.randint(len(test_loader))
print(f'La imagen muestreada representa un: {classes[test_loader.dataset[rnd_sample
image = test_loader.dataset[rnd_sample_idx][0]
image = (image - image.min()) / (image.max() -image.min() )
plot_figure(image)
```

```
La imagen muestreada representa un: bird
```

In [10]:
```
def plot_cifar10_grid():
    classes = test_loader.dataset.classes
    total_samples = 8
    plt.figure(figsize=(15,15))
    for label, sample in enumerate(classes):
        class_idxs = np.flatnonzero(label == np.array(test_loader.dataset.targets))
        sample_idxs = np.random.choice(class_idxs, total_samples, replace = False)
        for i, idx in enumerate(sample_idxs):
            plt_idx = i*len(classes) + label + 1
            plt.subplot(total_samples, len(classes), plt_idx)
            plt.imshow(test_loader.dataset.data[idx])
            plt.axis('off')

            if i == 0: plt.title(sample)
    plt.show()

plot_cifar10_grid()
```

3.2 Accuracy

Defining a function that computes the the classification accuracy of a model using a dataset loader (validation or test loader).

In [11]:
```
def accuracy_loader(model, loader):
    num_correct = 0
    num_total = 0
    cost = 0.
    model.eval()
    model = model.to(device=device)
    with torch.no_grad():
        for mb, (xi, yi) in enumerate(loader, 1):
            xi = xi.to(device=device, dtype=torch.float32)
            yi = yi.to(device=device, dtype=torch.long)
            scores = model(xi)
            cost += (F.cross_entropy(scores, yi.squeeze())).item()
            _, pred = scores.max(dim=1)
```

```
            num_correct += (pred == yi.squeeze()).sum().item()
            num_total += pred.size(0)

        return cost/mb, float(num_correct)/num_total
```

3.3 Training loop

Now we define a training functions that recives a neural network model, an optimizer, and a number of epochs. Which allows us to encapsulate the entire model training process.

In [12]:
```
def train(model, optimiser, train_loader, val_loader, epochs=10, scheduler=None):
    model = model.to(device=device)
    for epoch in range(epochs):
        train_correct_num  = 0.
        train_total = 0.
        train_cost_acum = 0

        model.train()
        for mb, (xi, yi) in enumerate(train_loader, 1):
            xi = xi.to(device=device, dtype=torch.float32)
            yi = yi.to(device=device, dtype=torch.long)

            scores = model(xi)
            cost = F.cross_entropy(input=scores, target=yi.squeeze())

            optimiser.zero_grad()
            cost.backward()
            optimiser.step()

            if scheduler:
                scheduler.step()

            train_correct_num += (torch.argmax(scores, dim=1) == yi.squeeze()).sum(
            train_total += scores.size(0)
            train_cost_acum += cost.item()

        val_cost, val_acc = accuracy_loader(model, val_loader)
        train_acc = float(train_correct_num)/train_total
        train_cost = train_cost_acum/mb

        print(f'Epoch:{epoch}, train cost: {train_cost:.6f}, val cost: {val_cost:.6
              f' train acc: {train_acc:.4f}, val acc: {val_acc:.4f}')
```

4. Linear model

In this section, two models are implemented and trained using PyTorch. First, a linear model is created to serve as a baseline classifier for the CIFAR-10 dataset.

This model typically consists of flattening the input images and applying a single fully connected layer that maps pixel values to the ten output classes. The purpose of this baseline model is to establish a reference performance level and verify that the training pipeline, loss computation, and optimization process are functioning correctly.

Network Architecture:

- **Input Layer:** 3,072 neurons ($32 \times 32 \times 3$ flattened RGB images).
- **Hidden Layer 1:** 1,024 neurons with BatchNorm, ReLU activation, and 0.3 Dropout.
- **Hidden Layer 2:** 512 neurons with BatchNorm, ReLU activation, and 0.3 Dropout.
- **Output Layer:** 10 neurons (one for each CIFAR-10 class).

Rationale:

1. **Input Size (3,072):** CIFAR-10 images are 32×32 pixels with 3 color channels. Unlike grayscale datasets, we must process the full RGB information.
2. **Regularization:** Given the high number of parameters (over 3 million in the first layer), we use Batch Normalization and Dropout to prevent the model from simply memorizing the training pixel patterns.

Hyperparameters:

- **Mini-batch Size:** 64
- **Learning Rate:** 1e-3
- **Epochs:** 20
- **Initialization:** Adam with Weight Decay (1e-4).

In [13]:
```
# --- Hyperparameters ---
hidden1 = 1024
hidden2 = 512
lr = 1e-3
epochs = 20

# --- LINEAR ARCHITECTURE ---
model1 = nn.Sequential(
    nn.Flatten(),
    nn.Linear(in_features=3072, out_features=hidden1),
    nn.BatchNorm1d(hidden1), # Helps gradients flow more effectively
    nn.ReLU(),
    nn.Dropout(0.3),         # Prevents it from memorizing specific pixels
    nn.Linear(in_features=hidden1, out_features=hidden2),
    nn.BatchNorm1d(hidden2),
    nn.ReLU(),
    nn.Dropout(0.3),
    nn.Linear(in_features=hidden2, out_features=10)
)

optimiser = torch.optim.Adam(model1.parameters(), lr=lr, weight_decay=1e-4)

# We apply the scheduler for smooth convergence
scheduler = torch.optim.lr_scheduler.OneCycleLR(optimiser, max_lr=lr,
                                                epochs=epochs,
                                                steps_per_epoch=len(train_loader))
```

```
# --- TRAINING ---
train(model1, optimiser, train_loader, val_loader, epochs, scheduler=scheduler)
```

```

```

In [14]:
```
test_cost, test_acc = accuracy_loader(model1, test_loader)
print(f'Test accuracy: {test_acc:.4f}')
```

```
Test accuracy: 0.5536
```

In [15]:
```
def plot_figure_normal(image):
    mean = torch.tensor([0.491, 0.482, 0.447])
    std = torch.tensor([0.247, 0.243, 0.261])
    image = image * std[:, None, None] + mean[:, None, None]

    image = torch.clamp(image, 0, 1)
    plt.imshow(np.transpose(image.numpy(), (1, 2, 0)))
```

```
    plt.axis('off')
    plt.show()
```

In [32]:
```
rnd_idx = np.random.randint(len(test_loader.dataset))
image_tensor, label_idx = test_loader.dataset[rnd_idx]
print(f'The sampled image represents a: {classes[label_idx]}')
plot_figure_normal(image_tensor)

model1.eval()
with torch.no_grad():
    xi = image_tensor.unsqueeze(0).to(device)
    scores = model1(xi)
    _, pred = scores.max(dim=1)

print(f'The value predicted by the linear model is {classes[pred.item()]}')
```

```
The sampled image represents a: bird
```

```
The value predicted by the linear model is airplane
```

The linear model (MLP) acts as our benchmark. Despite having miles of parameters, its performance stalls at around 55.2%.

Linear models treat the image as a flat vector, losing all spatial structure. If an object shifts a few pixels, for the linear model it becomes a completely different pattern. It lacks 'spatial invariance,' which makes it inefficient for computer vision compared to a CNN.

5. Sequential CNN

Next, a Convolutional Neural Network (CNN) is implemented using a sequential architecture. Unlike the linear model, the CNN can learn spatial features from images through

convolutional layers, which generally leads to improved classification performance on image datasets such as CIFAR-10.

After defining the CNN, the training function is called again to train this model for the specified number of epochs. The expectation is that the CNN achieves higher accuracy than the linear baseline model, demonstrating the advantage of convolutional feature extraction for image recognition tasks.

Network Architecture:

- **Block 1:** Two Conv layers (64 filters each, 3×3, padding=1), each followed by BatchNorm and ReLU, ending with 2×2 MaxPool and 0.2 Dropout.
- **Block 2:** Two Conv layers (128 filters each, 3×3, padding=1), each followed by BatchNorm and ReLU, ending with 2×2 MaxPool and 0.2 Dropout.
- **Fully Connected Classifier Layer 2:** Flatten $\rightarrow$ 512 neurons (ReLU) $\rightarrow$ 0.5 Dropout $\rightarrow$ 10 neurons (Output).

Rationale:

1. **Local Feature Extraction:** Convolutions allow the network to learn filters for edges, textures, and shapes regardless of their position in the image (spatial invariance).

2. **Double Convolutions:** Using two convolutional layers before pooling allows the network to develop more complex feature maps (e.g., combining edges into curves) before reducing resolution.

3. **Data Augmentation:** By training with random flips and crops, we force the network to learn robust features.

Hyperparameters:

- **Mini-batch Size:** 64
- **Learning Rate:** 5e-4
- **Epochs:** 40
- **Data Augmentation:** RandomHorizontalFlip and RandomCrop (padding=4).

In [17]:
```
# --- Hyperparameters ---
hidden_fc = 512
lr = 5e-4
epochs = 40
weight_decay = 1e-4

class CNNModelStable(nn.Module):
    def __init__(self):
        super().__init__()
        # BLOCK 1: 32x32 -> 16x16
        self.conv1_1 = nn.Conv2d(3, 64, 3, padding=1)
        self.bn1_1 = nn.BatchNorm2d(64)
        self.conv1_2 = nn.Conv2d(64, 64, 3, padding=1)
```

```
        self.bn1_2 = nn.BatchNorm2d(64)

        # BLOCK 2: 16x16 -> 8x8
        self.conv2_1 = nn.Conv2d(64, 128, 3, padding=1)
        self.bn2_1 = nn.BatchNorm2d(128)
        self.conv2_2 = nn.Conv2d(128, 128, 3, padding=1)
        self.bn2_2 = nn.BatchNorm2d(128)

In [20]:

```
test_cost, test_acc = accuracy_loader(model_stable, test_loader)
print(f'Test accuracy: {test_acc:.4f}')
```

```
Test accuracy: 0.8806
```

In [22]:

```
rnd_idx = np.random.randint(len(test_loader.dataset))
image_tensor, label_idx = test_loader.dataset[rnd_idx]
print(f'The sampled image represents a: {classes[label_idx]}')
plot_figure_normal(image_tensor)

model_stable.eval()
with torch.no_grad():
    xi = image_tensor.unsqueeze(0).to(device)
    scores = model_stable(xi)
    _, pred = scores.max(dim=1)

print(f'The value predicted by the CNN model is {classes[pred.item()]}')
```

```
The sampled image represents a: deer
```

```
The value predicted by the CNN model is deer
```

Final performance:

- Validation Accuracy: 87.9%.
- Test Accuracy: 88.06%.

The CNN architecture provides a massive gain of +31% over the linear model, proving it is the superior choice for image data.

6. Conclusions

The final results show a validation accuracy of 87.5% and a test accuracy of 80.8%, confirming that the model achieves strong generalization performance beyond the training data.

The significant improvement from 56% with the linear benchmark to 87% with the convolutional architecture clearly demonstrates the superiority of Convolutional Neural Networks for processing grid-structured data such as images. Unlike linear models, CNNs preserve spatial relationships and exploit local patterns, making them fundamentally more suitable for computer vision tasks.

Overfitting was effectively controlled through the combined use of Data Augmentation and Dropout. This strategy prevented the network from simply memorizing the training data and maintained a healthy gap between training and validation performance, indicating robust learning behavior.

From a technical standpoint, we also learned that the proper management of Batch Normalization statistics is critical. An incorrect implementation can severely damage performance—causing accuracy to collapse to nearly 10%—whereas a correct configuration with independent layers allows the model to fully leverage the computational power of the RTX 4060 GPU and reach its maximum potential.
